Introduction

The TMS HTML5 Controls Pack currently includes the TTIWHTML5Chart, TTIWHTML5PieChart, TTIWHTML5Gauge and TIWHTML5LocalStorage components.

The TTIWHTML5Chart is a chart component for web application development with the IntraWeb framework. The TTIWHTML5Chart uses HTML5/CSS3 to render data as various chart types: bar, line, area, stacked bar, stacked area and combinations of these chart types. By using the HTML5 Canvas and JavaScript code to render charts in any modern browser, no images are used and therefore bandwidth usage is minimal. The chart also heavily implements asynchronous updates and events. Chart series data, chart series properties and general chart properties can all be asynchronously updated. The TTIWHTML5PieChart has similar possibilities but represents pie charts that can have configurable start and end angles. This enables to show 360° pie charts, 180° pie charts or other variations.

The TMS TTIWHTML5Gauge is a gauge component for web application development with the IntraWeb framework. The TTIWHTML5Gauge uses HTML5/CSS3 to render a value in a circular or linear gauge. By using the HTML5 Canvas and JavaScript code to render a gauge in any modern browser, no images are used and therefore bandwidth usage is minimal. The gauge also heavily implements asynchronous updates and events. All properties can be updated asynchronously.

In this document you will find an overview of the components and their features, code snippets to quickly start using the component and an overview of properties, methods and events.

Availability

TMS HTML5 Controls Pack is available as VCL component for Delphi and C++Builder.

TMS HTML5 Controls Pack is available for Delphi 7,2007,2009,2010,XE,XE2 & C++Builder 2007,2009,2010,XE,XE2.

The IntraWeb framework 10.0, 11.0, 12.0 or 12.1 is required

TMS HTML5 Controls Pack has been designed for and tested with: Windows XP, Vista, and Windows 7.

Current version of TTIWHTML5Chart has been designed for and tested with Microsoft Internet

Explorer 9, Google Chrome 15, Firefox 5, Apple Safari for Mac OS-X, Apple Safari for iOS, Opera 11, WebKit.

List of included components

TTIWHTML5Chart: core chart component

TTIWHTML5PieChart: core pie chart component

TTIWHTML5Gauge: core gauge component

TTIWHTML5LocalStorage: core local storage component

TTIWHTML5Chart

TTIWHTML5Chart description

The TMS TTIWHTML5Chart component is designed to render various chart types in a browser using HTML5/CSS3/JavaScript. The component currently offers following chart types: bar, area, line, stacked area and stacked bar. Multiple series can be simultaneously shown in the chart.

TTIWHTML5Chart features

- Different chart modes: area, bar, line, stacked area and stacked bar.
- Automatic display of a legend in both vertical and horizontal mode.
- Annotations and value labels can be added to series points for any chart type.
- A 3D effect can be optionally applied to each chart type.
- Square, circle, rectangle or image markers on series points can be set for chart types: line, area and stacked area.
- A separate item layer is available to add any type of additional information on the chart at a position of choice, either on top of the series or below.
- Customizable text in X-axis, Y-axis and different X-axis, Y-axis per series.
- Automatic Y-axis range calculation or configurable range.
- Configurable helper lines and color banding.
- Asynchronous updatable single series point or entire series and asynchronous updates of series properties, chart properties.
- Different asynchronous events to handle clicks on various parts of the chart.
- Display of series points values as hint on mouse-over.
- Full asynchronous update support.

TTIWHTML5Chart architecture

The core part of the TTIWHTML5Chart is the series collection (1). As many series as required can be added to the chart via this collection. Each series in this collection can be separately configured. For each series, an X-axis (2) and Y-axis (3) can be displayed. Further, a legend (4), caption (5) and status line (6) are available. Finally, an item layer is a collection of items (7) that can be displayed along the series, either below or on top of the series is available.

TTIWHTML5Chart use

Getting started

From the Delphi repository select a new IntraWeb application template.

This is done by choosing: File -> New ->Other-> VCL for the Web Application Wizard.

From the component palette, select TTIWHTML5Chart and drop it on a form. This shows an empty chart. Add series via the collection editor shown upon clicking the property TTIWHTML5Chart.Series. The chart type for each series can here be set via THTML5ChartSerie.SerieType.

HTML5 Doctype

To correctly enable the use of HTML5 code in a browser that supports this technology, it is required to include the HTML5 Doctype: “<!DOCTYPE html>”.

In IntraWeb 11.0.47 or later this can be achieved by setting the DocType property of the ServerController form.

Example:

```
procedure TIWServerController.IWServerControllerBaseCreate(Sender:
TObject);
begin
  DocType := '<!DOCTYPE HTML>';
end;
```

In earlier version of IntraWeb this can be achieved by setting the PageContext.DocType property in your Form’s Render procedure.

Example:

```
procedure TIWForm1.IWAppFormRender(Sender: TObject);
begin
  PageContext.DocType := '<!DOCTYPE html>';
end;
```

When using a TIWTemplateProcessorHTML control as the Form’s LayoutMgr, the Doctype definition must be placed on the first line in the template html file.

Example:

```
<!DOCTYPE html>
<HTML>
<HEAD>
  <TITLE> My Template </TITLE>
</HEAD>
<BODY>
  {%TIWHTML5Chart1%}
</BODY>
</HTML>
```

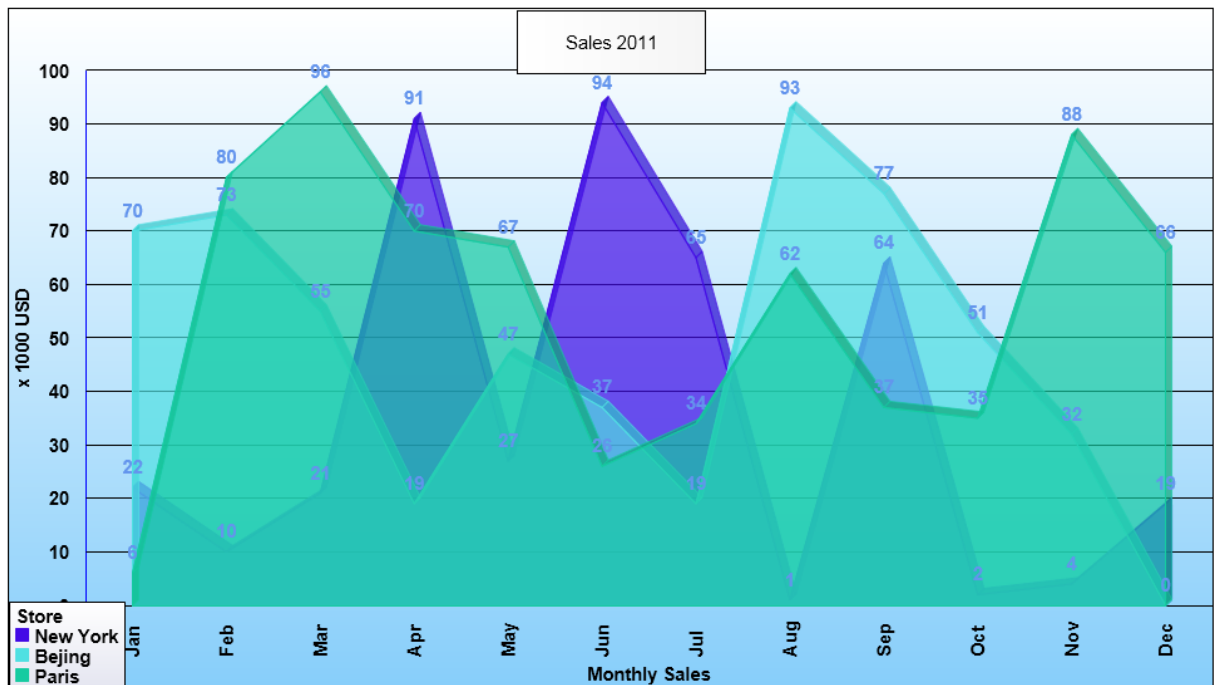

Please note that including the HTML5 Doctype on a form can influence the appearance and functionality of other controls on the same form which are not compatible or not fully compatible with this Doctype!

Chart Types

This is an overview of the chart types that can currently be set for each series in the chart:

- stArea

The screenshot below shows an example of an area chart type. The chart displays three area series with 3D option enabled, with opacity and with value labels. One item is added on the item layer to show the text “Sales 2011” in a rectangle. The location of the legend is set with Chart.Legend.Position = lpAbsolute and coordinates set via Chart.Legend.Left / Chart.Legend.Top.

- stBar

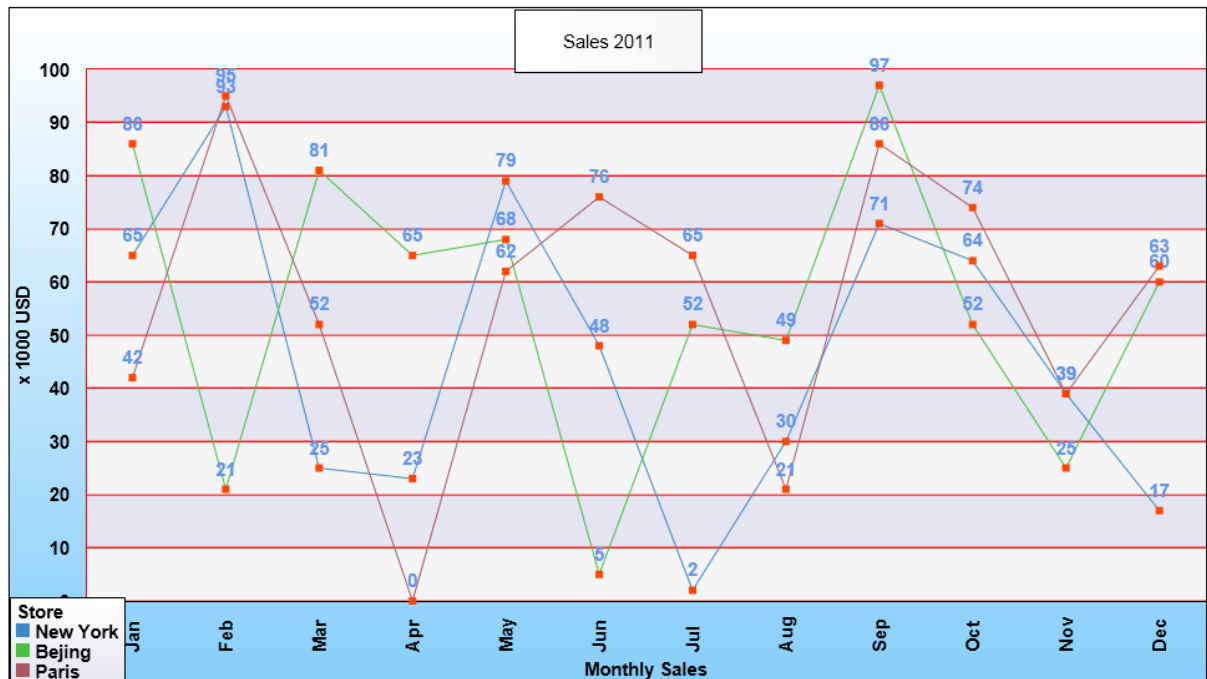

Below is an example of a bar chart type. This chart displays two series of data, with positive and negative values. A legend is added and legend items are displayed horizontally, set with `Chart.Legend.Orientation = oHorizontal`. One annotation is added to the series 0 at point 5.

Note also that in this sample, for each series, the range is set to the same value +80 / -80. This is done via `Chart.Series[index].RangeFrom / Chart.Series[index].RangeTo`. By specifying an identical range for all series, the chart has for each series an equal division of values along the Y-axis. If values of different series are in an entirely different range, it is no problem to define different values for `Chart.Series[index].RangeFrom / Chart.Series[index].RangeTo` for each series. The Y-axis can in such case display multiple ranges, i.e. a range for each displayed series instead of one common Y-axis as in the sample above.

- stLine

On the screenshot are 3 series of the line chart type. Square marker type was set for each series and value labels are shown. Note also the use of banding in the chart background. Banding is enabled with `Chart.Bands.Enabled = true` and colors for even bands and odd bands are set with `Chart.Bands.PrimaryColor / Charts.Bands.SecondaryColor`. The color of the helper lines is set with `Charts.Series[index].Yaxis. Color = clWebRed`.

- stStackedArea

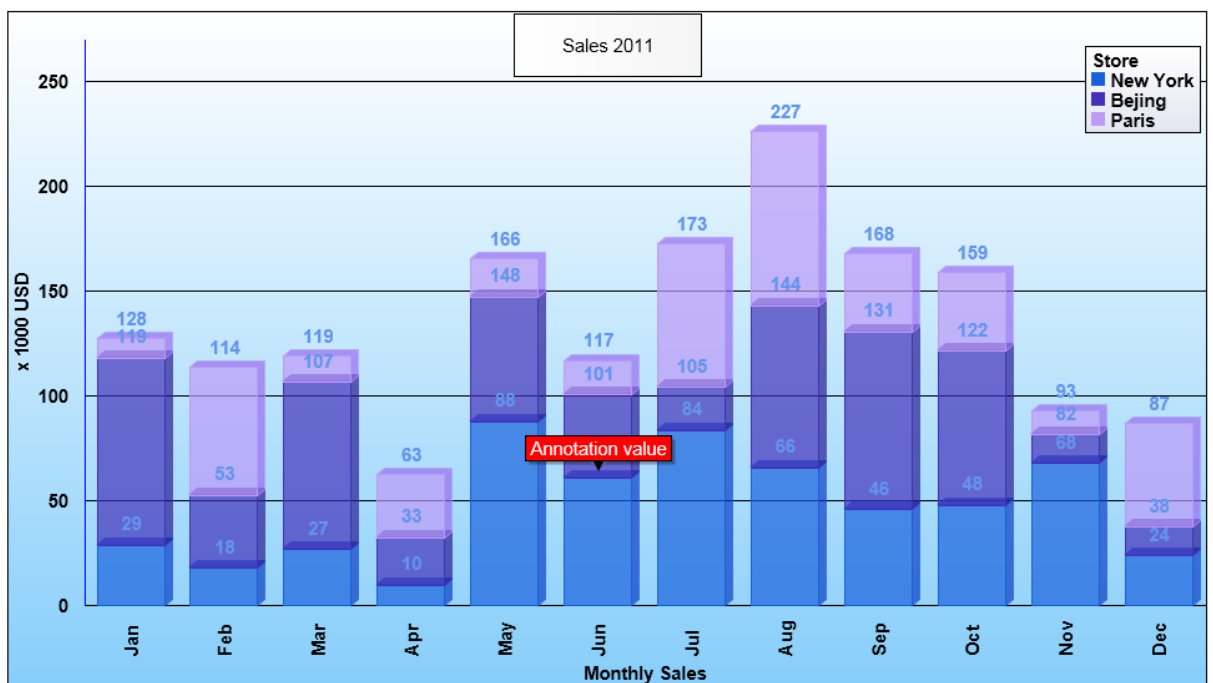

On the screenshot below, a stacked area chart is shown consisting of 3 series. The areas represent simply the sum of values of the series. The first series values are shown at the bottom, the last series values at the top. In this sample, annotations have been added to each point in each series.

Example code on how to fill the annotations with the values from each series can be found in the samples paragraph.

- stStackedBar

The last chart is of the stacked bar type. The chart shows 3 series of data with bars on top of each other for each series, summing the value. A 3D effect is enabled on the bar chart as well as opacity. Note that the labels on each part of the bar can either represent the value of each series or the summed value. In this example, the summed value is chosen and this was set with: `TIWHTML5Chart.Series[seriesindex].LabelType = ItSum`.

General chart settings

TIWHTML5Chart properties

- **BGColor:** Sets start color of the gradient for the chart background.
- **BGColorTo:** Sets end color of the gradient for the chart background.
- **BGGradientDirection:** Sets the gradient direction for the chart background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the text for the chart.
- **CommonZeroAxis:** When set to true, all zero lines are forced to one position on the chart. This makes sense when comparison of different series is demanded in a chart with positive and negative values.
- **HTML5Warning:** Sets the message displayed when the browser that is used to render the control does not support HTML5.
- **SelectedSerieIndex:** Sets or gets the index of the selected series. Note that the selected value point within a series is set via `TIWHTML5Chart.Series[SelectedSerieIndex].SelectedIndex`: integer.
- **ShowAnimation:** When set to true, the charts are displayed with animation. This means that when values are shown, an animation effect will show these from zero till the actual value. Note that for performance reasons, animation has been disabled for iOS. The CPU of these mobile devices is not sufficiently powerful to display a smooth animation.

Chart series

Adding/Removing series values

First open the series collection editor by clicking the `TIWHTML5Chart.Series` property in the Object Inspector. From here, series can be added or removed.

The equivalent in code is:

Adding a series:

```
var
  cs: THTML5ChartSerie:
begin
  cs := TIWHTML5Chart1.Series.Add;
  cs.SerieType := stArea;
  cs.Name := 'January';
  cs.YAxis.visible := False;
```

Removing a series:

```
TIWHTML5Chart1.Series.Delete (serieindex);
```

Select a series from the collection and its properties will be shown. The values for a series are organized under THTML5ChartSerie.Items. Click the property Items to open the series items collection editor and from here values can be added or removed. The value is set via THTML5ChartSerieItem.Value: double property and the X-axis text is set via THTML5ChartSerieItem.XAxis: string property.

To add a new value or remove an existing value programmatically, use the code as shown in the example below:

Adding a value to a series:

```
var
    csv: THTML5ChartSerieItem;

csv := TIWHTML5Chart1.Series[seriesindex].Items.Add;
csv.Value := Random(1000);
```

Removing a value from a series:

```
TIWHTML5Chart1.Series[seriesindex].Items.Delete(pointindex);
```

Customizing series appearance

The appearance of series can be further controlled via its properties. The following sample sets gradient start and end color, the opacity as well as the line color for the first series of an area chart. It also sets the delta between values displayed on the Y-axis for this series to a fixed value of 100.

```
begin
    TIWHTML5Chart1.Series[0].BGColor := clWebRed;
    TIWHTML5Chart1.Series[0].BGColorTo := clWebYellow;
    TIWHTML5Chart1.Series[0].LineColor := clWebBlack;
    TIWHTML5Chart1.Series[0].YAxis.Delta := 100;
    TIWHTML5Chart1.Series[0].Opacity := 200;
end;
```

The following code snippet sets the values that will be displayed in the X-axis for a series and by setting the XAxis.Rotate property to true, instructs that the chart should render these labels in

vertical direction:

```
for x := 0 to 11 do
begin
    TIWHTML5Chart1.Series[0].Items[x].XAxis := Months[x];
    TIWHTML5Chart1.Series[0].XAxis.Rotate := True;
end;
```

Chart series properties

For each series in the chart, an extensive configuration is possible. This is done via the THTML5ChartSerie class for instances in the TTIWHTML5Chart.Series collection.

THTML5ChartSerie properties

- **BGColor:** Sets start color of the gradient for the series background, i.e. color of bars in a bar chart or color of area in an area chart.
- **BGColorTo:** Sets end color of the gradient for the series background.
- **BGGradientDirection:** Sets the gradient direction for the series background. The gradient direction can be gdVertical or gdHorizontal.
- **ItemAlignment:** Determines the alignment of the item. Now fixed on iaCenter.
- **THTML5ChartSerieItem**
 - o **Defined:** Indicates if the item is displayed on the chart.
 - o **Name:** Can hold a name for the item.
 - o **Tag:** Stores an integer value. Tag is an integer property that has no predefined meaning. It can be used for storing an additional integer value, or it can be typecast to any value such as a component reference or a pointer.
 - o **Value:** Stores the chart value for the actual chart item.
- **LabelColor:** Sets the label text color.
- **LabelType:** Sets the label type. Following types are defined: ItNormal, ItSum. When ItSum is chosen with a stacked area or stacked bar chart, the shown labels are the sum up to that point in the chart. With ItNormal, the individual values are shown.
- **LineColor:** Sets the color of the lines in line series types or the border color for bar or area charts.

- **LineWidth:** Sets the width of the line in line series or the border width for bar or area charts.
- **MarkerColor:** Sets the color for series point markers when used in line or area charts.
- **MarkerImageUrl:** Sets the URL of the image file to use for the marker (when MarkerType is set to mtImage).
- **MarkerSize:** Sets the size of the marker.
- **MarkerType:** Sets the type of marker to use at series points for line or area charts. Following values are defined

mtNone: No marker is displayed.

mtCircle: A circular marker is displayed.

mtSquare: A square marker is displayed.

mtTriangle: A triangular marker is displayed.

mtImage: An image is used as marker.

- **Name:** Sets the name for the chart series. The name is used in the legend of the chart.
- **Opacity:** Sets the opacity for the bar or area of a series when these types are used. Opacity is a value between 0 and 255. 0 means fully transparent, 255 means fully opaque.
- **RangeFrom:** Sets the minimal value of a series.
- **RangeTo:** Sets the maximal value of a series. This property can be used to create manually some headroom on top of the chart, leaving enough space to display a legend.
- **SelectedBGColor:** Sets the color for the series point when it is in selected state.
- **SelectedIndex:** Sets or gets the index of the selected series point.
- **SelectedMarkerColor:** Sets the color of the marker when the series point is in selected state.
- **SerieType:** Sets the chart series type. Following types are defined: stArea, stBar, stLine, stStackedArea, stStackedBar. See the paragraph on series types for more information.
- **Show3D:** When set to true, shows the different series types with a 3D effect.
- **ShowLabels:** When set to true, shows text labels with the series point value.
- **Tag:** Stores an integer value. Tag is an integer property that has no predefined meaning. It can be used for storing an additional integer value, or it can be typecast to any value such as a component reference or a pointer.
- **XAxis:**
 - o **Font:** Sets the default font that will be used for the X-Axis values for the series.
 - o **Rotate:** When set to true, rotates the X-Axis values 90 degrees left for the series.

- **Visible:** When set to true, X-Axis values are displayed for the series.
- **YAxis:**
 - **Color:** Sets the color of the helper lines
 - **Delta:** Sets the delta between values where the value and a horizontal helper line is displayed. When delta is set to zero, this delta is internally calculated as the maximum series value minus the minimum series value in the series divided by 10.
 - **Font:** Sets the default font that will be used for the Y-Axis.
 - **Position:** Defines the position of the Y-Axis. Possible choices are: apLeft and apRight.
 - **Visible:** When set to true, Y-Axis values are displayed for the series.
 - **ZeroLineColor:** Sets the color of the zero line.
 - **ZeroLineWidth:** Sets the width of the zero line.

Chart annotations

Annotations offer a way to show additional information, other than the value to a series point. An annotation can be set as text, displayed in a rectangle with a background colour that can be specified and positioned near the series point. All annotations for the chart are bundled in the annotations collection and accessible via the property: `TTIHTML5Chart.Annotations`.

The sample below shows an area chart with one red annotation for one individual value (data point 5 in series 0).

Programmatically, an annotation can be added with the following code:

```
var
  ca: THTML5ChartAnnotation;
begin
  ca := TTIHTML5Chart1.Annotations.Add;
  ca.SerieIndex := 0;
  ca.PointIndex := 5;
  ca.Caption := 'Annotation value';
  ca.BGColor := clWebRED;
  ca.BGColorTo := clWebRED;
```

```
ca.BorderColor := clWebBLACK;  
end;
```

THTML5ChartAnnotation properties

- **BGColor:** Sets start color of the gradient for the annotation background.
- **BGColorTo:** Sets end color of the gradient for the annotation background.
- **BGGradientDirection:** Sets the gradient direction for the annotation background. The gradient direction can be gdVertical or gdHorizontal.
- **BorderColor:** Defines the border color for the annotation.
- **Caption:** Sets the text for the annotation.
- **Font:** Sets the default font that will be used for the annotation.
- **Name:** Can be set to give the annotation a name.
- **PointIndex:** Sets the data point index within a series to which the annotation belongs.
- **SerieIndex:** Sets the index of the series to which the annotation belongs.
- **Tag:** Stores an integer value. Tag is an integer property that has no predefined meaning. It can be used for storing an additional integer value, or it can be typecast to any value such as a component reference or a pointer.

Hints for series values

It is possible to show the values of series points only when the mouse hovers over the points. This capability is enabled by setting TTIWHTML5Chart.Hint.Visible to true. Further control over the appearance of these hints is found under TTIWHTML5Chart.Hint.

THTML5Hint properties

- **BGColor:** Sets start color of the gradient for the hint background.
- **BGColorTo:** Sets end color of the gradient for the hint background.
- **BGGradientDirection:** Sets the gradient direction for the hint background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the text for the hint.

- **Font:** Sets the default font that will be used for the hint.
- **LineColor:** Sets the color of the border of the hint.
- **LineWidth:** Sets the width of the border of the hint.
- **Visible:** When set to true, enables showing hints for series points.

Chart item layer

The `TTIWHTML5Chart.ItemLayer` is a collection of items that are positioned on the chart. An item can show text or an image. The item can be shown below the chart series or above the chart series. Further, the position and the size of the item can be set with `Top`, `Left`, `Height`, `Width` properties. Note that when `Height` and `Width` are zero, the size of the item is calculated automatically to fit the text set for the item.

Adding/Removing item layer items

Adding or removing an item layer item can be done either programmatically or at design-time. Double-click the `TTIWHTML5Chart.ItemLayer` property and the default collection editor will popup, allowing you to add new or remove existing item layer items.

To add a new or remove an existing item layer item programmatically use the code below.

Adding an item layer item:

```
var  
    ili: THTML5ChartItemLayerItem;  
  
begin
```

```
ili := TIWHTML5Chart1.ItemLayer.Add;  
ili.Caption := 'Sales 2011';  
ili.Top := 1;  
ili.Height := 50;  
ili.Width := 150;  
ili.Position := pBack;  
ili.Left := (TIWHTML5Chart1.Width - TIWHTML5Chart1.ItemLayer[0].Width)  
div 2;  
end;
```

Removing an itemlayer.item:

```
TIWHTML5Chart1.Itemlayer.Delete(itemindex);
```

TIHTML5ChartItemLayerItem properties

- **BGColor:** Sets start color of the gradient for the item layer item background.
- **BGColorTo:** Sets end color of the gradient for the item layer item background.
- **BGGradientDirection:** Sets the gradient direction for the item layer item. The gradient direction can be gdVertical or gdHorizontal.
- **BorderColor:** Defines the border color for the item layer item.
- **Caption:** Sets the text for the item layer item.
- **Font:** Sets the default font that will be used for the item layer item.
- **Height:** Sets the height for the item layer item.
- **ImageUrl:** Sets the URL for a picture for the item layer item (when Shape = slmage).
- **Left:** Sets the left position for the item layer item.
- **Name:** Sets the name for the item layer item.
- **Position:** Defines if the item layer item is displayed on top of the chart series (pFront) or below the chart series (pBack).
- **Shape:** Selects the shapes for the item, possible choices are: rectangle, circle, image or square.
- **Tag:** Stores an integer value. Tag is an integer property that has no predefined meaning. It can be used for storing an additional integer value, or it can be typecast to any value such as a component reference or a pointer.

- **Top:** Sets the top position for the item layer item.
- **Width:** Sets the width for the item layer item.

Chart legend

TTIHTML5Chart can show a legend for its series in the chart. The names of series as shown in the legend-box, is set via the chart series THTML5ChartSerie.Name property. Together with the series name, a small box is shown in front of the name in the same color as the series.

THTML5Legend properties

- **BGColor:** Sets start color of the gradient for the legend background.
- **BGColorTo:** Sets end color of the gradient for the legend background.
- **BGGradientDirection:** Sets the gradient direction for the legend background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the header text for the legend.
- **Font:** Sets the default font that will be used for the legend.
- **Left:** Sets the left position for the legend (when Position = lpAbsolute).
- **LineColor:** Sets the color of the border of the legend.
- **LineWidth:** Sets the width of the border of the legend.
- **Opacity:** Sets the opacity for the legend area. Opacity is a value between 0 and 255. 0 means fully transparent, 255 means fully opaque.
- **Orientation:** Sets the orientation of the legend. The orientation can be oVertical or oHorizontal.
- **Position:** Sets the position of the legend in the chart. The position can be lpLeft, lpRight, lpAbsolute or lpNone:
 - lpLeft: Show the legend top left in the chart.
 - lpRight: Show the legend top right in the chart.
 - lpNone: Do not show the legend.
 - lpAbsolute: Show the legend at position TTIHTML5Chart.Legend.Left, TTIHTML5Chart.Legend.Top.
- **Top:** Sets the top position for the legend (when Position = lpAbsolute).

Chart script events

It is possible to associate JavaScript code when specific events occur in the chart. This way, custom code can be called from the browser to extend functionality without requiring communication with the server. This saves bandwidth and increases the responsiveness of the web application. The place where the JavaScript code can be specified is all grouped under the class property `TTIHTML5Chart.ScriptEvents`. These are simple `TStringList` instances holding the JavaScript code that will be executed.

THTML5ChartScriptEvents properties

- **AnnotationClick(annotationIndex):** Holds JavaScript code executed when an annotation is clicked. The returned value is an integer with the index of the annotation in the `TTIHTML5Chart.Annotations` collection.
- **Click:** Holds JavaScript code executed when the chart area is clicked.
- **DoubleClick:** Event occurs when the chart is double-clicked.
- **ItemLayerClick(itemLayerIndex):** Holds JavaScript code executed when the `ItemLayer` item is clicked. The returned value is an integer with the index of the `Item` in the `ItemLayer` collection.
- **LegendClick(serieIndex, itemIndex):** Holds JavaScript code executed when the legend is clicked. Returned values are the index of the series within the series collection, and the index of the item within the items collection.
- **SerieClick(serieIndex, itemIndex):** Holds JavaScript code executed when clicked on a series. Returned values are the index of the series within the series collection, and the index of the item within the items collection.
- **SerieDoubleClick(serieIndex, itemIndex):** Holds JavaScript code executed when a series is double-clicked. Returned values are the index of the series within the series collection, and the index of the item within the items collection.

Chart X-Axis

Other than the series X-axis values, a common X-axis text can be specified for the chart. If for multiple series X-axis values are set, the common X-axis text will be displayed at the bottom. The settings for this common X-axis text are grouped under `TTIHTML5Chart.XAxis`.

TTHTML5ChartXAxis properties

- **Caption:** Sets the text for the X-axis.
- **Color:** Sets the color for the X-axis lines.
- **Font:** Sets the default font that will be used for the X-axis text.
- **LineWidth:** Sets the width of the lines drawn for each series point on the X-axis.
- **Visible:** When set to true, the X-axis caption will be displayed.

Chart Y-Axis

Other than the series Y-axis values, a common Y-axis text can be specified for the chart. If for multiple series Y-axis values are displayed, the common Y-axis text will be displayed at the left most position. The settings for this common Y-axis text are grouped under `TTIHTML5Chart.YAxis`.

TTHTML5ChartYAxis Properties

- **Caption:** Sets the text for the Y-axis.
- **Color:** Sets the color for the Y-axis lines.
- **DecimalPrecision:** Sets the number of decimals to use for the Y-axis automatically generated values.
- **Font:** Sets the default font that will be used for the Y-axis.
- **LineWidth:** Sets the width of the border of the Y-axis.
- **Visible:** When set to true, the common Y-axis text is displayed.

Chart bands

The bands property offers the opportunity to define alternating colors for the chart background.

THTML5Bands Properties

- **Enabled:** When true, colour banding is applied.
- **PrimaryColor:** Sets the colour of odd bands.
- **SecondaryColor:** Sets the colour of even bands.

Chart methods

procedure AsyncUpdateAllValues();

Sends all series values asynchronously to the browser.

The following example shows how to change all series types for a chart.

```
for seriesidx := 0 to MaxSeries-1 do  
  TIWHTML5Chart1.Series[seriesidx].SerieType := stBar;  
TIWHTML5Chart1.AsyncUpdateAllValues();
```

procedure AsyncUpdateChangedValues();

Sends back all series values that were changed between the previous asynchronous update call and the new AsyncUpdateChangedValues() call.

procedure AsyncUpdateSingleValue(SerieIndex, ItemIndex: integer; Value: double);

Sends a single value at ItemIndex position in the values collection of series SerieIndex in the Series collection to the browser.

```
TIWHTML5Chart1.AsyncUpdateSingleValue(0,2, random(1000));
```

Please notice that “Async*” methods can only be used from within asynchronous events! Those asynchronous events may come from any IntraWeb Control (even IWHTML5Chart).

From non-asynchronous events, no specific update calls are required as the chart will be automatically fully re-rendered.

Example of valid code:

```
procedure TIWForm4.IWButton5AsyncClick(Sender: TObject;
    EventParams: TStringList);
begin
    TIWHTML5Chart1.Series[0].Items[5].Value := 5;
    TIWHTML5Chart1.AsyncUpdateAllValues;
end;
```

Chart events

There are two types of events: synchronous and asynchronous events. Synchronous events trigger a complete page refresh. Asynchronous events on the other hand only transfer specific data to the server without invoking a full page refresh. It will depend on the event handling code for asynchronous events how the control will be updated.

- **OnAnnotationClick(Sender: TObject; AnnotationIndex: Integer):**

Event triggered when an annotation is clicked. The parameter AnnotationIndex returns the index of the annotation in the TTIWHTML5Chart.Annotations collection.

- **OnAsyncAnnotationClick:** Asynchronous version of the OnAnnotationClick event.

- **OnClick(Sender: TObject):** Event triggered when the chart background is clicked.

- **OnAsyncClick:** Asynchronous version of the OnClick event.

- **OnDoubleClick(Sender: TObject):** Event triggered when the chart background is double-clicked.

- **OnAsyncDoubleClick:** Asynchronous version of the OnDoubleClick event.

- **OnItemLayerClick(Sender: TObject; ItemLayerIndex: Integer):**

Event triggered when an item in the ItemLayer collection is clicked. The ItemLayerIndex parameter returns the index of this item in the ItemLayer collection.

- **OnAsyncItemLayerClick:** Asynchronous version of the OnItemLayerClick event.

- **OnSerieClick(Sender: TObject; SerieIndex, PointIndex: integer):**

Event triggered when a data point of a series is clicked. The SerieIndex parameter returns the index of the series in the TTIWHTML5Chart.Series collection and the PointIndex returns the index of the data point in the TTIWHTML5Chart.Series[SerieIndex].Items collection.

- **OnAsyncSerieClick:** Asynchronous version of the OnSerieClick event.

- **OnLegendClick(Sender: TObject; SerieIndex: Integer):**

Event triggered when a series name is clicked in the legend. The SerieIndex parameter returns the index of the series in the TTIWHTML5Chart.Series collection.

- **OnAsyncLegendClick:** Asynchronous version of the OnLegendClick event.

- **OnSerieDoubleClick(Sender: TObject; SerieIndex, PointIndex: integer):**

Event triggered when a data point of a series is double-clicked. The SerieIndex parameter returns the index of the series in the TTIWHTML5Chart.Series collection and the PointIndex returns the index of the data point in the TTIWHTML5Chart.Series[SerieIndex].Items collection.

- **OnAsyncSerieDoubleClick:** Asynchronous version of the OnSerieDoubleClick event.

THTML5Chart Sample code

Sample 1

This sample code adds values to all series in the chart and sets a common RangeFrom/RangeTo for all series based on the minimum and maximum value in all chart series:

```
var
  ChartMin, ChartMax, ChartVal: Double
  xidx, yidx: integer;
begin
  ChartMin := 100;
  ChartMax := 0;
  for yidx := 0 to MaxSeries-1 do
  begin
    for xidx := 0 to 11 do
    begin
      chartval := Random(100);
      if chartval < ChartMin then
        ChartMin := chartval;
      if chartval > ChartMax then
        ChartMax := chartval;

      TIWHTML5Chart1.Series[yidx].Items[xidx].Value := chartval;
    end;
  end;

  for yidx := 0 to MaxSeries-1 do
  begin
    TIWHTML5Chart1.Series[yidx].RangeFrom := ChartMin;
    TIWHTML5Chart1.Series[yidx].RangeTo := ChartMax;
  end;

  TIWHTML5Chart1.AsyncUpdateAllValues();
end;
```

Sample 2

In this code snippet, annotations are created that contain the series values:

```
var
  ca: THTML5ChartAnnotation;
  xidx, yidx: integer;
```

```
begin
  TIWHTML5Chart1.Annotations.Clear;

  for yidx := 0 to MaxSeries-1 do
  begin
    for xidx := 0 to 11 do
    begin
      ca := TIWHTML5Chart1.Annotations.Add;
      ca.SerieIndex := yidx;
      ca.PointIndex := xidx;
      ca.Caption := FloatToStr(TIWHTML5Chart1.Series[ca.SerieIndex
].Items[ca.PointIndex].Value);
      ca.BGColor := clWebOldLace;
      ca.BGColorTo := TIWHTML5Chart1.Series[yidx].BGColor;
      ca.BorderColor := clWebBLACK;
      ca.Font.Color := clWebBLACK;
    end;
  end;
end;
```

Sample 3

Configuring the chart to display a Y-Axis for each series and change its color and font color:

```
var
  yidx: integer;
begin
  for yidx := 0 to At1Series-1 do
  begin
    TIWHTML5Chart1.Series[Yidx].YAxis.Visible := True;
    TIWHTML5Chart1.Series[Yidx].Yaxis.Color :=
TIWHTML5Chart1.Series[Yidx].BGColor;
    TIWHTML5Chart1.Series[Yidx].YAxis.Font.Color :=
TIWHTML5Chart1.Series[Yidx].BGColor;
    IWButton14.Caption := 'Multi Y-Axis';
  end;
  TIWHTML5Chart1.AsyncUpdateAllValues();
end;
```

Sample 4

Setting different chart types for different series:

```
const
    Charts: array[0..4] of TTIWSeriesType
    =(stArea, stBar, stLine, stStackedArea, stStackedBar);

var
    yidx: integer;

begin
    for yidx := 0 to 4 do
        TIWHTML5Chart1.Series[yidx].SerieType := charts[yidx];
    end;
```

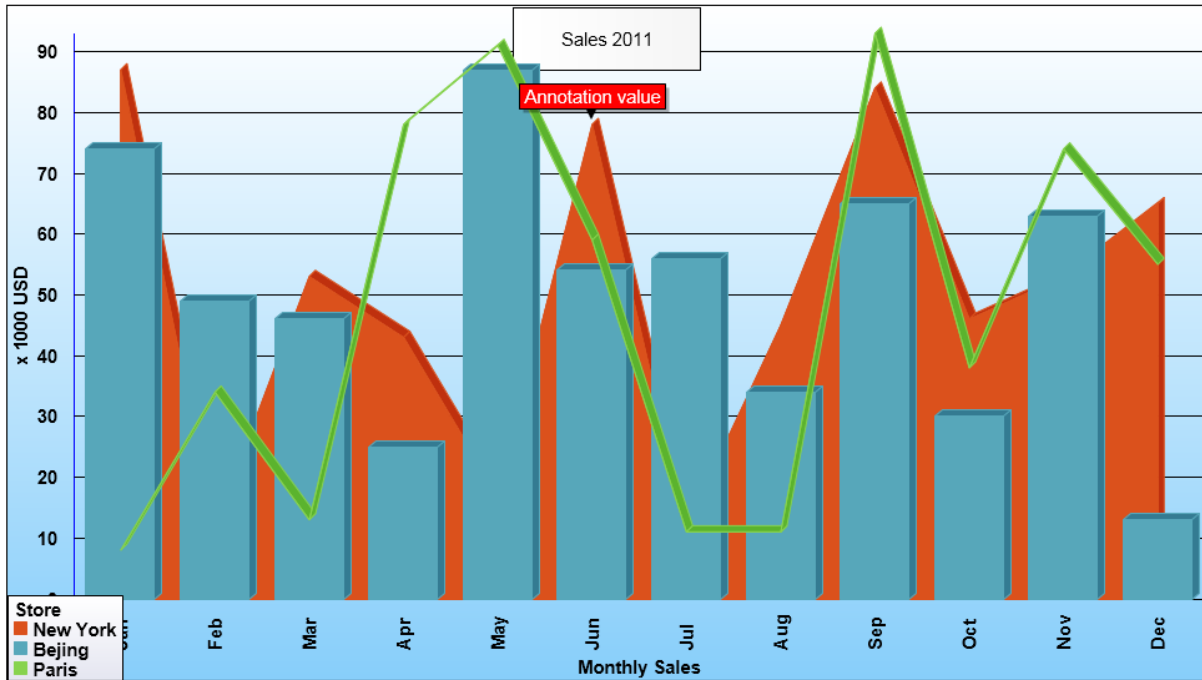

THTML5Chart Advanced techniques

When designing a chart without connection between the values of the different series, each series will use a maximum of the drawing area. This can be confusing, because values of different weights can stand one next to another. As shown in the next example, one has the possibility to show multiple Y-Axis and (colored) helper lines to improve readability.

An example on how to do this in program code can be found in the samples paragraph.

Each series can have their specific chart type.

An example on how to do this in program code can be found in the samples paragraph.

Main screen after some property value changes:

TMS IntraWeb HTML5 Chart Configuration Demo

Series Set the number of Series that are displayed and configure the Range and Type of the Series. Serie Count: <input type="text" value="2"/> Range: <input type="text" value="Positive"/> Type: <input type="text" value="Bar"/>	Items Set the amount of Items per Serie and configure the type of Markers and the Alignment. Item Count: <input type="text" value="10"/> Markers: <input type="text" value="None"/> Alignment: <input type="text" value="Center"/>	Events Async event messages are displayed here: Event message
Effects <input checked="" type="checkbox"/> 3D Gradients: <input type="text" value="Horizontal"/> <input checked="" type="checkbox"/> Opacity <input type="checkbox"/> Animation	Extras <input type="checkbox"/> Annotations <input type="checkbox"/> ItemLayer Legend: <input type="text" value="Center"/> <input checked="" type="checkbox"/> Labels <input type="text" value="Vertical"/> <input checked="" type="checkbox"/> Banding	Info All updates are done asynchronously. For this demo, colors and item values are randomized with each refresh.

TTIWHTML5Chart drill down demo

The TMSIWHTML5ChartDemo program shows a typical single level drill down scenario with TTIWHTML5Chart.

The chart is shown in 3D bar series style. Other series type can be selected in the IWComboBox in this demo.

When a column of the chart is clicked, via drill down, a detailed chart is shown, in this case the sales distribution among brands for the selected month. Clicking on a column asynchronously adds an annotation to a series point with some extra information on the bar represented value. Clicking

outside a bar will move back to the main chart.

Main screen

TMS IntraWeb HTML5 Chart

Chart type:

Drill down chart after a column was clicked. A click on one bar in this chart displays an annotation on the selected series value.

TMS IntraWeb HTML5 Chart

TTIHTML5PieChart

TTIHTML5PieChart description

The TMS TTIHTML5PieChart component is designed to render pie charts in a browser using HTML5/CSS3/JavaScript. The component can display a full circle or a partial circle chart.

TTIHTML5PieChart features

- Display one or more exploded segments.
- Display pie chart as a full circle or a partial circle.
- Automatic display of a legend in both vertical and horizontal mode.
- A shadow effect can be optionally applied.
- Apply different animation effects.
- Display segment values as hint on mouse-over.
- Asynchronous events to handle clicks on segments.
- Full asynchronous update support.

TTIHTML5PieChart architecture

- 1) Optional caption text
- 2) Automatically generated and configurable legend
- 3) Exploded pie segment
- 4) Default pie segment
- 5) Optional label

TTIHTML5PieChart use

Getting started

From the Delphi repository select a new IntraWeb application template.

This is done by choosing: File -> New ->Other-> VCL for the Web Application Wizard.

From the component palette, select TTIHTML5PieChart and drop it on a form. This shows an empty chart. Add segments via the collection editor shown upon clicking the property TTIHTML5PieChart.Segments.

HTML5 Doctype

To correctly enable the use of HTML5 code in a browser that supports this technology, it is required to include the HTML5 Doctype: “<!DOCTYPE html>”.

In IntraWeb 11.0.47 or later this can be achieved by setting the DocType property of the ServerController form.

Example:

```
procedure TIWServerController.IWServerControllerBaseCreate(Sender:
TObject);
begin
  DocType := '<!DOCTYPE HTML>';
end;
```

In earlier version of IntraWeb this can be achieved by setting the PageContext.DocType property in your Form’s Render procedure.

Example:

```
procedure TIWForm1.IWAppFormRender(Sender: TObject);
begin
  PageContext.DocType := '<!DOCTYPE html>';
end;
```

When using a TIWTemplateProcessorHTML control as the Form’s LayoutMgr, the Doctype definition must be placed on the first line in the template html file.

Example:

```
<!DOCTYPE html>
<HTML>
<HEAD>
  <TITLE> My Template </TITLE>
</HEAD>
<BODY>
  {%TIWHTML5Chart1%}
</BODY>
</HTML>
```

Please note that including the HTML5 Doctype on a form can influence the appearance and functionality of other controls on the same form which are not compatible or not fully compatible with this Doctype!

General PieChart settings

TIWHTML5PieChart properties

- **AnimationType:** Sets the type of animation that is used when the pie chart is displayed.
 - o **atNone:** No animation is used
 - o **atEndAngle:** The EndAngle is animated
 - o **atRadius:** The Radius is animated
- **BGColor:** Sets start color of the gradient of the control background.
- **BGColorTo:** Sets end color of the gradient of the control background.
- **BGGradientDirection:** Sets the gradient direction of the controls background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the caption text for the control.
- **ExplodedOffset:** Sets the offset of a Segment when the State property is set to ssExploded.
- **HTML5Warning:** Sets the message displayed when the browser that is used to render the control does not support HTML5.
- **PieCenterX:** Sets the left position of the pie chart center coordinate. When set to -1, the left position is automatically set to the center of the control width.
- **PieCenterY:** Sets the top position of the pie chart center coordinate. When set to -1, the top position is automatically set to the middle of the control height.
- **PieEndAngle:** Sets the ending angle of the pie chart circle.
- **PieRadius:** Sets the radius of the pie chart circle.
- **PieStartAngle:** Sets the starting angle of the pie chart circle.
- **SelectedIndex:** Sets the index of the currently selected segment.
- **ShowShadow:** Sets if a shadow effect is applied to the pie chart.

Hints for segments

It is possible to show the values of segments when the mouse hovers over them. This capability is enabled by setting `TTIWHTML5PieChart.Hint.Visible` to true. Further control over the appearance of these hints is found under `TTIWHTML5PieChart.Hint`.

THTML5Hint properties

- **BGColor:** Sets start color of the gradient for the hint background.
- **BGColorTo:** Sets end color of the gradient for the hint background.
- **BGGradientDirection:** Sets the gradient direction for the hint background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the text for the hint.
- **Font:** Sets the default font that will be used for the hint.
- **LineColor:** Sets the color of the border of the hint.
- **LineWidth:** Sets the width of the border of the hint.
- **Visible:** Sets if a hint is displayed when the mouse is hovering a segment.

PieChart legend

TTIHTML5PieChart can show a legend for its segments in the chart. The text of a segment as shown in the legend-box, is set via the segment THTML5PieChartSegment.Text property. Together with the segment text, a small box is shown in front of the name in the same color as the segment.

THTML5Legend properties

- **BGColor:** Sets start color of the gradient for the legend background.
- **BGColorTo:** Sets end color of the gradient for the legend background.
- **BGGradientDirection:** Sets the gradient direction for the legend background. The gradient direction can be gdVertical or gdHorizontal.
- **Caption:** Sets the header text for the legend.
- **Font:** Sets the default font that will be used for the legend.
- **Left:** Sets the left position for the legend (when Position = lpAbsolute).
- **LineColor:** Sets the color of the border of the legend.
- **LineWidth:** Sets the width of the border of the legend.
- **Opacity:** Sets the opacity for the legend area. Opacity is a value between 0 and 255. 0 means fully transparent, 255 means fully opaque.

- **Orientation:** Sets the orientation of the legend. The orientation can be oVertical or oHorizontal.
- **Position:** Sets the position of the legend in the chart. The position can be lpLeft, lpRight, lpAbsolute or lpNone:
 - lpLeft: Show the legend top left in the chart.
 - lpRight: Show the legend top right in the chart.
 - lpNone: Do not show the legend.
 - lpAbsolute: Show the legend at position TIWHTML5PieChart.Legend.Left, TIWHTML5PieChart.Legend.Top.
- **Top:** Sets the top position for the legend (when Position = lpAbsolute).

PieChart segments

Adding/Removing segment values

First open the segments collection editor by clicking the TTIWHTML5PieChart.Segments property in the Object Inspector. From here, segments can be added or removed.

The equivalent in code is:

Adding a series:

```
var
    cs: THTML5ChartSegment;
begin
    cs := TIWHTML5PieChart1.Segments.Add;
```

```
cs.Value := 10;
end;
```

Removing a series:

```
TIWHTML5PieChart1.Segments.Delete(segmentindex);
```

Customizing segment appearance

The appearance of segments can be further controlled via its properties. The following sample sets gradient start and end color, the line color for the first segment of a pie chart. It also makes the segment label visible.

```
begin
  TIWHTML5PieChart1.Segments[0].BGColor := clWebRed;
  TIWHTML5PieChart1.Segments[0].BGColorTo := clWebYellow;
  TIWHTML5PieChart1.Segments[0].LineColor := clWebBlack;
  TIWHTML5PieChart1.Segments[0].ShowLabel := True;
end;
```

PieChart segment properties

The segment configuration is done via the THTML5PieChartSegment class for instances in the TIWHTML5PieChart.Segments collection.

THTML5PieChartSegment properties

- **BGColor:** Sets start color of the gradient for the series background.
- **BGColorTo:** Sets end color of the gradient for the series background.
- **HintText:** Sets the text that is displayed in the hint of the segment.
- **LabelFont:** Sets the label font.
- **LegendText:** Sets the text that is displayed in the legend item relative to the segment.
- **LineColor:** Sets the color of the lines in line series types or the border color for bar or area charts.
- **LineWidth:** Sets the width of the line in line series or the border width for bar or area charts.

- **Name:** Sets the name for the chart series.
- **Opacity:** Sets the opacity for the segment. Opacity is a value between 0 and 255. 0 means fully transparent, 255 means fully opaque.
- **ShowLabel:** When set to true, shows a text label next to the segment.
- **Tag:** Stores an integer value. Tag is an integer property that has no predefined meaning. It can be used for storing an additional integer value, or it can be typecast to any value such as a component reference or a pointer.
- **Text:** Sets the text that is displayed in the Label of the segment.
- **Value:** The value of the segment. This value defines the size of the segment relative to the other segments.

PieChart methods

procedure AsyncUpdateAllValues(Animated: boolean);

Sends all property values asynchronously to the browser.

The Animated parameter sets if the updated control is displayed using an animation effect as configured with the AnimationType property.

The following example shows how to change the value of a segment:

```
procedure TIWForm4.IWButton5AsyncClick(Sender: TObject;
  EventParams: TStringList);
begin
  TIWHTML5PieChart1.Segments[0].Value := 20;
  TIWHTML5PieChart1.AsyncUpdateAllValues(false);
end;
```

PieChart script events

It is possible to associate JavaScript code when specific events occur in the control. This way, custom code can be called from the browser to extend functionality without requiring communication with the server. This saves bandwidth and increases the responsiveness of the web application. The place where the JavaScript code can be specified is all grouped under the class property `TTIWHTML5PieChart.ScriptEvents`. These are simple `TStringList` instances holding the JavaScript code that will be executed.

TTIWHTML5PieChartScriptEvents properties

- **LegendClick(index):** Holds JavaScript code executed when the legend is clicked. Returned value is the index of the segment within the segments collection.
- **SegmentClick(index):** Holds JavaScript code executed when a segment is clicked. Returned value is the index of the segment within the segments collection.

PieChart events

There are two types of events: synchronous and asynchronous events. Synchronous events trigger a complete page refresh. Asynchronous events on the other hand only transfer specific data to the server without invoking a full page refresh. It will depend on the event handling code for asynchronous events how the control will be updated.

- **OnSegmentClick(Sender: TObject; Index: integer):**
Event triggered when a segment is clicked. The Index parameter returns the index of the segment in the TTIWHTML5PieChart.Segments collection.
- **OnAsyncSegmentClick:** Asynchronous version of the OnSegmentClick event.
- **OnLegendClick(Sender: TObject; Index: Integer):**
Event triggered when a segment name is clicked in the legend. The Index parameter returns the index of the segment in the TTIWHTML5PieChart.Segments collection.
- **OnAsyncLegendClick:** Asynchronous version of the OnLegendClick event.

Example:

```

procedure TIWForm4.TIWHTML5PieChart1AsyncSegmentClick(Sender: TObject;
EventParams: TStringList; Index: Integer);
var
    I: integer;
begin
    for I := 0 to TIWHTML5PieChart1.Segments.Count - 1 do
        begin
            TIWHTML5PieChart1.Segments[I].State := ssNormal;
        end;

    TIWHTML5PieChart1.Segments[Index].State := ssExploded;

    TIWHTML5PieChart1.AsyncUpdateAllValues(false);
end;
    
```

THTML5PieChart Sample code

Sample 1

This sample code demonstrates how to create a half-circle pie chart:

```
TIWHTML5PieChart1.PieStartAngle := 180;
TIWHTML5PieChart1.PieEndAngle := 360;
```

TTIWHTML5PieChart demos

TMSIWHTML5PieChartConfigDemo

The TMSIWHTML5PieChartConfigDemo program shows the various configuration possibilities of the TTIWHTML5PieChart component. It allows to interactively set various properties and the changes will be immediately reflected via asynchronous updates.

Main screen:

TMS IntraWeb HTML5 PieChart Config Demo

All updates are done asynchronously
 Click on a segment or a legend item to change it to exploded state.

PieChart configuration		
Segments:	4	<input type="checkbox"/> Half circle
Legend:	Left	<input checked="" type="checkbox"/> Labels
Animation:	EndAngle	<input checked="" type="checkbox"/> Shadow

TMS HTML5 PieChart

TTIHTML5Gauge

TTIHTML5Gauge description

The TMS TTIHTML5Gauge component is designed to render various gauge types in a browser using HTML5/CSS3/JavaScript. The component currently offers following gauge types: circular, linear horizontal and linear vertical. Multiple Sections and SetPoints can also be displayed.

The gauge can be used as a read-only control but also features optional mouse interaction to change the needle position.

TTIHTML5Gauge features

- Different gauge types: circular, linear horizontal and linear vertical
- Triangle, arrow, line, double line or image needle type can be set for linear gauge types
- Triangle, square, circle or line SetPoints types can be set for all gauge types
- Multiple configurable sections can be added for all gauge types
- Minimum and maximum with divisions and subdivisions
- Informative DialText and formatted value display
- Asynchronous event to handle clicks on the gauge
- Full asynchronous update support

TTIHTML5Gauge architecture

- 1) Needle: The needle can be fully customized and points to the current value.
- 2) DialText (gtCircular only): The DialText can be useful to provide information on the purpose of the gauge. Some samples: Speed, C°, KPH, MPH ...
- 3) Value (gtCircular only): The value is displayed below the DialText. The value can optionally be formatted or hidden.
- 4) The minimum and maximum values can be changed and the property DivisionCount allows setting the number of divisions from minimum to maximum.
- 5) The property DivisionCount also specifies the tick marks. The property SubDivisionCount is the number of tick marks between two divisions.
- 6) Sections: the Sections collection is used to mark special areas where the value in that range has a different meaning than the value outside that range by means of a special background color.
- 7) SetPoints: the SetPoints collection can be used to indicate special values on the gauge.

TTIHTML5Gauge use

Getting started

From the Delphi repository select a new IntraWeb application template.

This is done by choosing: File -> New ->Other-> VCL for the Web Application Wizard.

From the component palette, select TTIHTML5Gauge and drop it on a form. Set the desired Value and GaugeType.

HTML5 Doctype

To correctly enable the use of HTML5 code in a browser that supports this technology, it is required to include the HTML5 Doctype: “<!DOCTYPE html>”.

In IntraWeb 11.0.47 or later this can be achieved by setting the DocType property of the ServerController form.

Example:

```
procedure TIWServerController.IWServerControllerBaseCreate(Sender:
TObject);
begin
  DocType := '<!DOCTYPE HTML>';
end;
```

In earlier version of IntraWeb this can be achieved by setting the PageContext.DocType property in your Form’s Render procedure.

Example:

```
procedure TIWForm1.IWAppFormRender(Sender: TObject);
begin
  PageContext.DocType := '<!DOCTYPE html>';
end;
```

When using a TIWTemplateProcessorHTML control as the Form’s LayoutMgr, the Doctype definition must be placed on the first line in the template html file.

Example:

```
<!DOCTYPE html>
<HTML>
<HEAD>
  <TITLE> My Template </TITLE>
</HEAD>
<BODY>
  {%TIWHTML5Chart1%}
</BODY>
</HTML>
```

Please note that including the HTML5 Doctype on a form can influence the appearance and functionality of other controls on the same form which are not compatible or not fully compatible with this Doctype!

General gauge settings

TIWHTML5Gauge properties

- **BGColor:** Sets start color of the gradient for the gauge background.
- **BGColorTo:** Sets end color of the gradient for the gauge background. Setting the BGColorTo value to `clNone` means a solid color will be used as background color.
- **BGGradientDirection:** Sets the gradient direction for the gauge background. The gradient direction can be `gdVertical` or `gdHorizontal`.
- **DecimalPrecision:** Sets the number of decimals used for the Division text labels.
- **DialText:** Sets the text for the gauge, displayed when the gauge type is `gtCircular`.
- **DivisionColor:** Sets the color of the division tick marks.
- **DivisionCount:** Sets the number of divisions displayed between the minimum and maximumvalue.
- **DivisionWidth:** Sets the width of the division tick marks.
- **EndAngle:** (`gtCircular` only) Sets the ending angle of the gauge circle.
- **GaugeType:** Sets the type of gauge that is displayed.

`gtCircular`:

`gtLinearHorizontal`:

gtLinearVertical:

- **HTML5Warning:** Sets the message displayed when the browser that is used to render the control does not support HTML5.
- **MaximumValue:** Sets the maximum value displayed on the gauge.
- **MinimumValue:** Sets the minimum value displayed on the gauge.
- **Padding:** (gtLinearHorizontal & gtLinearVertical only) Sets the padding size between the border and the first/last division.
- **ShowDialText:** (gtCircular only) Sets if the DialText is displayed or not.
- **ShowValue:** (gtCircular only) Sets if the Value is displayed or not.
- **StartAngle:** (gtCircular only) Sets the starting angle of the gauge circle.
- **SubDivisionColor:** Sets the color of the subdivision tick marks.
- **SubDivisionCount:** Sets the number of subdivision tick marks between each division tick mark.
- **SubDivisionWidth:** Sets the width of the subdivision tick marks.
- **Value:** Sets the value, i.e. position where the needle is displayed. For gtCircular gauges the value can also be displayed as text on the gauge.
- **ValueFormat:** (gtCircular only) Sets the formatting of the value displayed below the DialText

Gauge Arc

The Arc properties are used to configure the arc on which the Gauge is displayed. For the circular gauge type the arc is displayed between the StartAngle and EndAngle, for the linear gauge types the arc always covers the full width or height of the control.

Gauge Arc properties

THTML5GaugeArc properties

- **BGColor:** Sets the background color of the arc.
- **EndAngle:** (gtCircular only) Sets the end angle in degrees of the Arc.
- **StartAngle:** (gtCircular only) Sets the start angle in degrees of the Arc.
- **Width:** Sets the width of the spacing above the tick marks that is available for Sections and SetPoints.

Gauge Needle

The needle can be fully customized and points to the current value.

Gauge Needle properties

THTML5GaugeNeedle properties

- **BGColor:** Sets the background color of the Needle.
- **ImageURL:** (gtLinearHorizontal & gtLinearVertical only) Sets the image used to display the Needle, if Shape is set to nsImage.
- **InnerCenterColor:** (gtCircular only) Sets the background color of the Needle's inner circle.
- **InnerCenterColorTo:** (gtCircular only) Sets the gradient background color of the Needle's inner circle.
- **InnerCenterOpacity:** (gtCircular only) Sets the opacity of the Needle's inner circle.
- **OuterCenterColor:** (gtCircular only) Sets the background color of the Needle's outer circle.

- **OuterCenterColorTo:** (gtCircular only) Sets the gradient background color of the Needle's outer circle.
- **OuterCenterOpacity:** (gtCircular only) Sets the opacity of the Needle's outer circle.
- **Shape:** (gtLinearHorizontal & gtLinearVertical only) Sets the shape of the needle: nsArrow, nsDoubleLine, nsImage, nsLine, nsTriangle.
- **ShineColor:** (gtCircular only) Sets the secondary "shine" color of the Needle.

Gauge Sections

Sections are displayed as a colored band above the division tick marks. Each section has customizable StartValue and EndValue, the section is displayed between these values.

Adding/Removing Sections

First open the Sections collection editor by clicking the TTIWHTML5Gauge.Sections property in the Object Inspector. From here, Sections can be added or removed.

The equivalent in code is:

Adding a section:

```
var
    gs: THTML5GaugeSection;

begin

    gs := TIWHTML5Gauge1.Sections.Add;
    gs.StartValue := 75;
    gs.EndValue := 100;
    gs.BGColor := clWebRed;
```

Removing a section:

```
TIWHTML5Gauge1.Sections.Delete(sectionindex);
```

Gauge Section properties

THTML5GaugeSection properties

- **BGColor:** Sets background color of the Section.
- **EndValue:** Sets the end value (as absolute number between minimum & maximum) of the Section.
- **StartValue:** Sets the start value (as absolute number between minimum & maximum) of the Section.
- **Visible:** Defines whether the Section is displayed or not.

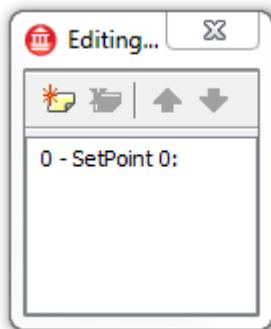

Gauge SetPoints

SetPoints are used to indicate special values and are displayed above the division tick marks. Each SetPoint has a customizable Value which indicates where the SetPoint will be displayed.

Adding/Removing SetPoints

First open the SetPoints collection editor by clicking the `TTIHTML5Gauge.SetPoints` property in the Object Inspector. From here, SetPoints can be added or removed.

The equivalent in code is:

Adding a SetPoint:

```
var
    sp: THTML5GaugeSetPoint;

begin

    sp := TTIHTML5Gauge1.SetPoints.Add;
    sp.Value := 50;
    sp.BGColor := clWebBlack;
    sp.Shape := psTriangle;
```

Removing a section:

```
TIWHTML5Gauge1.SetPoints.Delete (setpointindex);
```

Gauge SetPoints properties

TIHTML5GaugeSetPoints properties

- **BGColor:** Sets the background color of the SetPoint.
- **Shape:** Sets the shape of the SetPoint: psCircle, psLine, psSquare, psTriangle.
- **Value:** Sets the value of the SetPoint.
- **Visible:** Defines whether the SetPoint is displayed or not.

Chart methods

procedure AsyncUpdateAllValues();

Sends back all property values asynchronously to the browser.
The gauge is completely re-rendered asynchronously.

Please notice that the AsyncUpdateAllValues method can only be used from within asynchronous events!

Those asynchronous events may come from any IntraWeb Control (even IWHTML5Gauge).

From non-asynchronous events, no specific update calls are required as the chart will be automatically fully re-rendered.

Example:

```
procedure TIWForm4.IWButton5AsyncClick(Sender: TObject;  
    EventParams: TStringList);  
begin  
    TIWHTML5Gauge1.Value := 10;  
    TIWHTML5Gauge1.AsyncUpdateAllValues;  
end;
```

Gauge script events

It is possible to associate JavaScript code when a click event occurs in the gauge. This way, custom code can be called from the browser to extend functionality without requiring communication with

the server. This saves bandwidth and increases the responsiveness of the web application. The place where the JavaScript code can be specified is all grouped under the class property `TTIWHTML5Chart.ScriptEvents`. These are simple `TStringList` instances holding the JavaScript code that will be executed.

TTIWHTML5ChartScriptEvents properties

- **Click(value):** Holds JavaScript code executed when the gauge is clicked. The returned value contains the corresponding Value of the position where the click event occurred.

Gauge events

There are two types of events: synchronous and asynchronous events. Synchronous events trigger a complete page refresh. Asynchronous events on the other hand only transfer specific data to the server without invoking a full page refresh. It will depend on the event handling code for asynchronous events how the control will be updated.

- **OnClick(Value: Double):** Event triggered when the gauge is clicked. The Value parameter contains the corresponding Value of the position where the click event occurred.
- **OnAsyncClick:** Asynchronous version of the OnClick event.

Example:

```
procedure TIWForm4.TIWHTML5Gauge1AsyncClick(Sender: TObject;  
    EventParams: TStringList; Value: Double);  
begin  
    TIWHTML5Gauge1.Value := Value;  
    TIWHTML5Gauge1.AsyncUpdateAllValues;  
end;
```

THTML5Gauge Sample code

Sample 1

This sample code demonstrates how to create a half-circle gauge:

```
with TIWHTML5Gauge1 do
begin
  MaximumValue := 100;
  MinimumValue := 0;
  StartAngle := 180;
  EndAngle := 360;
  Arc.StartAngle := 190;
  Arc.EndAngle := 350;
  DivisionCount := 5;
  ShowDialText := false;
  ShowValue := false;
end;
```

TTIWHTML5Gauge demo

The TMSIWHTML5GaugeDemo program shows the various configuration possibilities of the TTIWHTML5Gauge component. It allows to interactively set various properties and the changes will be immediately reflected via asynchronous updates in the displayed gauges.

TTIWHTML5LocalStorage

TTIWHTML5LocalStorage description

The TMS TTIWHTML5LocalStorage component is designed to store client-side data in a browser using HTML5/CSS3/JavaScript. This is a non-visual component.

TTIWHTML5LocalStorage features

- Access the browser's local storage data from an IntraWeb application.
- Full asynchronous read, write, update and remove support.

TTIWHTML5LocalStorage use

Getting started

From the Delphi repository select a new IntraWeb application template.

This is done by choosing: File -> New ->Other-> VCL for the Web Application Wizard.

From the component palette, select TTIWHTML5LocalStorage and drop it on a form.

HTML5 Doctype

To correctly enable the use of HTML5 code in a browser that supports this technology, it is required to include the HTML5 Doctype: "<!DOCTYPE html>".

In IntraWeb 11.0.47 or later this can be achieved by setting the DocType property of the ServerController form.

Example:

```
procedure TIWServerController.IWServerControllerBaseCreate(Sender:
TObject);
begin
  DocType := '<!DOCTYPE HTML>';
end;
```

In earlier version of IntraWeb this can be achieved by setting the PageContext.DocType property in your Form's Render procedure.

Example:

```
procedure TIWForm1.IWAppFormRender(Sender: TObject);  
begin  
    PageContext.DocType := '<!DOCTYPE html>';  
end;
```

When using a TIWTemplateProcessorHTML control as the Form's LayoutMgr, the Doctype definition must be placed on the first line in the template html file.

Example:

```
<!DOCTYPE html>  
<HTML>  
<HEAD>  
    <TITLE> My Template </TITLE>  
</HEAD>  
<BODY>  
    {%TIWHTML5Chart1%}  
</BODY>  
</HTML>
```

Please note that including the HTML5 Doctype on a form can influence the appearance and functionality of other controls on the same form which are not compatible or not fully compatible with this Doctype!

General LocalStorage settings

TIWHTML5LocalStorage properties

- **HTML5Warning:** Sets the message displayed when the browser that is used to render the control does not support HTML5 local storage.

LocalStorage methods

procedure ClearItems();

Removes all items that are currently stored in the browser's local storage.

procedure GetItem(Name: string);

Retrieves the item from local storage for which the name is equal to the Name parameter value. Once the item has been retrieved, the OnAsyncGetItem event gets fired.

procedure GetItems(Names: TStringList);

Retrieves the items from local storage for which the name is equal to one of the string values in the Names parameter. Once the items have been retrieved, the OnAsyncGetItems event gets fired.

procedure GetAllItems();

Retrieves all items that are currently stored in the browser's local storage. Once all items have been retrieved, the OnAsyncGetAllItems event gets fired.

procedure RemoveItem(Name: string);

Removes the item from local storage for which the name is equal to the Name parameter value.

procedure SetItem(Name, Value: string);

Updates the value of the item in local storage with the Value parameter value for which the name is equal to the Name parameter value. If no corresponding item is found in local storage, a new item is automatically inserted using the Name and Value parameter values.

Note that since all data is stored client-side, it will only be available on a per browser basis. Data stored in one browser can't be accessed in another browser. The data is also domain dependent, which means data that is saved by a web application located on a certain domain will not be available for a web application on another domain.

LocalStorage events

- **OnAsyncGetItem(Sender: TObject; EventParams: TStringList, Name, Value: string):**

Asynchronously triggered event after the GetItem procedure has been called. Returns the Name and Value of the requested item.

- **OnAsyncGetItems(Sender: TObject; EventParams, Items: TStringList):**

Asynchronously triggered event after the GetItems procedure has been called. Returns a TStringList containing the name-value pairs of all requested items.

- **OnAsyncGetAllItems(Sender: TObject; EventParams, Items: TStringList):**

Asynchronously triggered event after the GetAllItems procedure has been called. Returns a TStringList containing the name-value pairs of all items currently stored in local storage.

- **OnAsyncHTML5Error(Sender: TObject; EventParams: TStringList, ErrorMessage: string):**

Asynchronously triggered event if a JavaScript error occurs while accessing local storage. Returns the error message.

For example, an error can be raised when the local storage functionality has been disabled in the browser preferences or when the preserved space for local storage data has been exceeded.

TIWHTML5LocalStorage sample code

Sample 1

This sample code demonstrates how to save and/or update items in local storage:

```
TIWHTML5LocalStorage1.SetItem('Name', editName.Text);  
TIWHTML5LocalStorage1.SetItem('Street', editStreet.Text);  
TIWHTML5LocalStorage1.SetItem('City', editCity.Text);  
TIWHTML5LocalStorage1.SetItem('Zip', editZip.Text);
```

Sample 2

This sample code demonstrates how to load multiple items from local storage:

1. Add the name of all required items to a TStringList which is passed to GetItems as a parameter.

```

procedure LoadItems;
var
  items: TStringList;
begin
  items := TStringList.Create;

  try

    items.Add('Name');
    items.Add('Street');
    items.Add('City');
    items.Add('Zip');
    TIWHTML5LocalStorage1.GetItems(items);
  finally
    items.Free;
  end;
end;

```

2. Assign the OnAsyncGetItems event and use the Items parameter to retrieve the values of the requested items.

```

procedure TIWHTML5LocalStorage1AsyncGetItems(Sender: TObject;
  EventParams, Items: TStringList);
var
  I: Integer;
begin
  for I := 0 to Items.Count - 1 do
  begin
    if Items.Names[I] = 'Name' then
      editName.Text := Items.ValueFromIndex[I];

    if Items.Names[I] = 'Street' then
      editStreet.Text := Items.ValueFromIndex[I];

    if Items.Names[I] = 'City' then
      editCity.Text := Items.ValueFromIndex[I];

    if Items.Names[I] = 'Zip' then
      editZip.Text := Items.ValueFromIndex[I];
  end;
end;

```

TTIWHTML5LocalStorage demos

TMSIWHTML5LocalStorageDemo

The TMSIWebHTML5LocalStorageDemo program shows how to automatically fill a form from data saved in local storage. It also allows updating or removing the data.

TMS IntraWeb HTML5 LocalStorage Demo

Form data saved in local storage will be loaded automatically the next time this page is accessed.
